By combining measurements of parallax, proper motion (the apparent motion of a star across the sky, usually measured in seconds of arc per year) and the Doppler shifting of spectral lines, we can work out a star's actual velocity through space. A good example is Barnard's star, a magnitude 9.5 red dwarf star in the constellation Ophiucus, which has the largest known proper motion of any star.

The parallax is  $p = 0.54901''$  so its distance is

$$(1) \quad d = \frac{1}{p} = 1.82146 \text{ pc} = 5.9408 \text{ ly} = 5.62032 \times 10^{16} \text{ m}$$

Its proper motion is  $\mu = 10.3577'' \text{ yr}^{-1}$  which works out to

$$(2) \quad \mu = 10.3577 \frac{\pi}{3600 \times 180} = 5.021555 \times 10^{-5} \text{ rad yr}^{-1}$$

$$(3) \quad = \frac{5.021555 \times 10^{-5}}{3600 \times 24 \times 365.25} = 1.59123 \times 10^{-12} \text{ rad s}^{-1}$$

At the distance of Barnard's star, this gives a transverse velocity component of

$$(4) \quad v_{\theta} = d\mu = 8.9432 \times 10^4 \text{ m s}^{-1}$$

In the spectrum, the hydrogen alpha ( $H\alpha$ ) line is observed at a wavelength of 656.034 nm, and the rest  $H\alpha$  wavelength is 656.28 nm. As the star's wavelength is shorter than the rest wavelength, it is blue-shifted and Barnard's star is moving towards us. The (relativistic) Doppler shift formula for a speed  $v$  that is positive for approaching objects is

$$(5) \quad \bar{\lambda} = \lambda \sqrt{\frac{1 - v/c}{1 + v/c}}$$

For non-relativistic speeds,  $v \ll c$  and we can Taylor-expand this formula to get

$$(6) \quad \bar{\lambda} = \lambda - \frac{\lambda}{c}v + \mathcal{O}\left(\frac{v^2}{c^2}\right)$$

Keeping only terms first order in  $v/c$  we get

$$(7) \quad v = \frac{\lambda - \bar{\lambda}}{\lambda}c$$

For Barnard's star this gives a radial velocity of

$$(8) \quad v_r = \frac{656.28 - 656.034}{656.28} (2.99792 \times 10^8)$$

$$(9) \quad = 1.12374 \times 10^5 \text{ m s}^{-1}$$

The actual speed of Barnard's star through space, relative to Earth, is

$$(10) \quad v = \sqrt{v_r^2 + v_\theta^2} = 1.4362 \times 10^5 \text{ m s}^{-1}$$
