Here are a few examples of calculating the Fourier coefficients for some special cases.

Example 1. Consider the infinite slot problem with the boundary at $x = 0$ consisting of a conducting strip with a constant potential of V_0 . In this case we get

$$c_n = \frac{2V_0}{a} \int_0^a \sin \frac{n\pi y}{a} dy \quad (1)$$

$$= \frac{2V_0}{n\pi} (1 - \cos n\pi) \quad (2)$$

The coefficients are thus zero for even n and $4V_0/\pi$ for odd n :

$$c_n = \begin{cases} 0 & n \text{ even} \\ \frac{4V_0}{n\pi} & n \text{ odd} \end{cases} \quad (3)$$

The potential is thus

$$V(x, y) = \frac{4V_0}{\pi} \sum_{n=1,3,5,\dots}^{\infty} \frac{e^{-n\pi x/a}}{n} \sin \frac{n\pi y}{a} \quad (4)$$

Example 2. Now suppose the boundary at $x = 0$ consists of two conducting strips, insulated from each other and from the infinite sheets. The first strip, from $y = 0$ to $y = a/2$ has a constant potential V_0 while the other strip, from $y = a/2$ to $y = a$ is held at potential $-V_0$.

Here, the coefficients c_n are given by

$$c_n = \frac{2V_0}{a} \left[\int_0^{a/2} \sin \frac{n\pi y}{a} dy - \int_{a/2}^a \sin \frac{n\pi y}{a} dy \right] \quad (5)$$

$$= \frac{2V_0}{n\pi} \left[1 - 2 \cos \frac{n\pi}{2} + \cos n\pi \right] \quad (6)$$

If n is odd, this comes out to zero. If n is even, there are two cases. First, if $n = 2, 6, 10, \dots$ the term in brackets is 4. If $n = 4, 8, 12, \dots$ the term in brackets is zero. Thus we get

$$c_n = \begin{cases} 0 & n \text{ odd} \\ \frac{8V_0}{n\pi} & n = 2, 6, 10 \dots \\ 0 & n = 4, 8, 12 \dots \end{cases} \quad (7)$$

Thus the potential is

$$V(x, y) = \frac{8V_0}{\pi} \sum_{n=2,6,10,\dots}^{\infty} \frac{e^{-n\pi x/a}}{n} \sin \frac{n\pi y}{a} \quad (8)$$

$$= \frac{8V_0}{\pi} \sum_{n=0}^{\infty} \frac{e^{-(4n+2)\pi x/a}}{4n+2} \sin \frac{(4n+2)\pi y}{a} \quad (9)$$

where in the last line we've changed the index of summation since the non-zero terms in the first sum are just those with $n = 4m + 2$ starting at $m = 0$.

Example 3. The infinite slot with the strip at $x = 0$ held at potential V_0 has the solution

$$V(x, y) = \frac{4V_0}{\pi} \sum_{n=1,3,5,\dots}^{\infty} \frac{e^{-n\pi x/a}}{n} \sin \frac{n\pi y}{a} \quad (10)$$

For a conductor, the surface charge density can be found from the derivative taken normal to the surface:

$$\sigma = -\epsilon_0 \left. \frac{\partial V}{\partial n} \right|_{x=0} \quad (11)$$

In this case, the normal to the surface is the x direction, so we get

$$\sigma = -\epsilon_0 \frac{4V_0}{\pi} \sum_{n=1,3,5,\dots}^{\infty} \left(-\frac{n\pi}{a} \right) \frac{e^{-n\pi x/a}}{n} \sin \frac{n\pi y}{a} \Big|_{x=0} \quad (12)$$

$$= \epsilon_0 \frac{4V_0}{a} \sum_{n=1,3,5,\dots}^{\infty} \sin \frac{n\pi y}{a} \quad (13)$$

This looks fine except for the problem that the series doesn't converge. Consider $y = a/2$. The series is then a sum of an alternating sequence of $+1$ and -1 . The original series for the potential does converge at $x = 0$ due to the n in the denominator. Not sure what the solution to this is.
