If magnetic monopoles did exist, we could consider the behaviour of magnetic charges q_m. We could postulate a Coulomb's law for them:

$$\mathbf{F}=\frac{\mu_0}{4\pi}\frac{q_{m_1}q_{m_2}\left(\mathbf{r}_2-\mathbf{r}_1\right)}{\left|\mathbf{r}_2-\mathbf{r}_1\right|^3} \tag{1}$$

Griffiths sets the problem of 'working out' the force law for a magnetic charge passing through electric and magnetic fields. This strikes me as rather difficult, since the Lorentz force law for electric charges is essentially a postulate of the theory (confirmed by experiment); it was never derived. The simplest equivalent magnetic force law would seem to be something like

$$\mathbf{F}=q_m\mathbf{B}+q_m\mathbf{v}\times\mathbf{E} \tag{2}$$

We do need to check the units, however. First, what are the units of a magnetic charge q_m? The units of μ_0 are m kg s^{-2} A^{-2} so the Coulomb force law gives us

$$\text{kg m s}^{-2}=\text{m kg s}^{-2}\text{ A}^{-2}\left[q_m\right]^2\text{m}^{-2} \tag{3}$$

so the units of q_m must be A m = Coulomb m s^{-1}, that is, charge times velocity. How does this fit with our proposed Lorentz-like force law? The units of $\mathbf{B}$ are kg m s^{-2} A^{-1} m^{-1}, so $q_m\mathbf{B}$ has the units of force, so that term seems OK.

For the second term, we know that electric charge times electric field give force, so that means that $q_m\mathbf{v}\times\mathbf{E}$ has the units of force times velocity squared, so we need to divide by some constant velocity squared. Since we know that $\mu_0\varepsilon_0=1/c^2$ this seems a logical choice, so we can propose

$$\mathbf{F}=q_m\mathbf{B}+\mu_0\varepsilon_0q_m\mathbf{v}\times\mathbf{E}=q_m\mathbf{B}+\frac{q_m}{c^2}\mathbf{v}\times\mathbf{E} \tag{4}$$

In fact, the commonly accepted form is

$$\mathbf{F} = q_m\mathbf{B} - \frac{q_m}{c^2}\mathbf{v}\times\mathbf{E} \tag{5}$$

I could not find a 'derivation' of this result; rather it seems that this form is adopted to make this force law invariant under a duality transformation.
