The potentials V and $\mathbf{A}$ that give rise to a particular configuration of fields $\mathbf{E}$ and $\mathbf{B}$ are not unique. For example, for a point charge at the origin, the usual potentials would be

$$V = \frac{q}{4\pi\varepsilon_0 r} \tag{0.1}$$

$$\mathbf{A} = 0 \tag{0.2}$$

but as we've seen, the potentials

$$V(\mathbf{r},t) = 0 \tag{0.3}$$

$$\mathbf{A}(\mathbf{r},t) = -\frac{1}{4\pi\varepsilon_0}\frac{qt}{r^2}\hat{\mathbf{r}} \tag{0.4}$$

give rise to the same fields. The question arises: what is the most general set of potentials that give a particular configuration of fields? That is, what changes can we make to V and $\mathbf{A}$ without changing $\mathbf{E}$ and $\mathbf{B}$?

The fields can be calculated from the potentials via the equations

$$\mathbf{B} = \nabla\times\mathbf{A} \tag{0.5}$$

$$\mathbf{E} = -\nabla V - \frac{\partial\mathbf{A}}{\partial t} \tag{0.6}$$

We can't multiply V and $\mathbf{A}$ by anything and leave the fields unchanged, but we might be able to add something. Suppose we add a vector function $\alpha(\mathbf{r},t)$ to $\mathbf{A}$ and a scalar function $\beta(\mathbf{r},t)$ to V:

$$\mathbf{A}' = \mathbf{A}+\alpha \tag{0.7}$$

$$V' = V+\beta \tag{0.8}$$

To get the same magnetic field, we must have

$$\mathbf{B} = \nabla\times\mathbf{A} \tag{0.9}$$
$$= \nabla\times\mathbf{A}' \tag{0.10}$$
$$= \nabla\times(\mathbf{A}+\alpha) \tag{0.11}$$
$$\nabla\times\alpha = 0 \tag{0.12}$$

Since its curl is zero, we can write α as the gradient of a scalar field:

$$\alpha(\mathbf{r},t) = \nabla\lambda'(\mathbf{r},t) \tag{0.13}$$

We also have to get the same electric field $\mathbf{E}$ so

$$\mathbf{E} = -\nabla V - \frac{\partial\mathbf{A}}{\partial t} \tag{0.14}$$
$$= -\nabla(V+\beta) - \frac{\partial(\mathbf{A}+\alpha)}{\partial t} \tag{0.15}$$
$$\nabla\beta + \frac{\partial\alpha}{\partial t} = 0 \tag{0.16}$$

Combining these results, we get

$$\nabla\left(\beta + \frac{\partial\lambda'}{\partial t}\right) = 0 \tag{0.17}$$

The term in parentheses must not depend on position (since its gradient is identically zero everywhere), but it might depend on time. Define this term to be $k(t)$; then

$$\beta = k(t) - \frac{\partial\lambda'}{\partial t} \tag{0.18}$$

If we define

$$\lambda \equiv \lambda' - \int_0^t k(t')\,dt' \tag{0.19}$$

then

$$\beta = -\frac{\partial\lambda}{\partial t} \tag{0.20}$$

Since λ and λ' differ only by a function of time (and not of space), their gradients are equal, so we can use λ in place of λ' in 0.13 without changing

α. Therefore we can change the potentials as follows, without changing the fields they produce:

$$\mathbf{A}' = \mathbf{A} + \nabla\lambda \tag{0.21}$$

$$V' = V - \frac{\partial\lambda}{\partial t} \tag{0.22}$$

where $\lambda = \lambda(\mathbf{r}, t)$ is an arbitrary scalar field. Such a change to the potentials is called a *gauge transformation*.

Example. Earlier, we saw the unusual potentials 0.3 and 0.4 for a point charge at the origin. We can transform them using the gauge function

$$\lambda = -\frac{qt}{4\pi\varepsilon_0 r} \tag{0.23}$$

We get

$$\nabla\lambda = \frac{qt}{4\pi\varepsilon_0 r^2}\hat{\mathbf{r}} \tag{0.24}$$

$$\frac{\partial\lambda}{\partial t} = -\frac{q}{4\pi\varepsilon_0 r} \tag{0.25}$$

so the new potentials are

$$V = \frac{q}{4\pi\varepsilon_0 r} \tag{0.26}$$

$$\mathbf{A} = 0 \tag{0.27}$$

which is the more usual set of potentials 0.1 and 0.2 for a point charge.
