And now for a general relativistic look at the standard physics problem of throwing an object up in a gravitational field. Suppose we start at radius $r = r_0$ and throw up the object so that it comes to rest momentarily at $r = r_1$ before turning around and falling back to r_0 . What is the total proper time (as measured by the object) in this trip?

We begin by working out the energy e . For an object at rest at $r = r_1$:

$$e = \left(1 - \frac{2GM}{r_1}\right) \frac{dt}{d\tau} \quad (1)$$

$$= \left(1 - \frac{2GM}{r_1}\right) u^t \quad (2)$$

$$= \left(1 - \frac{2GM}{r_1}\right) \left(1 - \frac{2GM}{r_1}\right)^{-1/2} \quad (3)$$

$$= \left(1 - \frac{2GM}{r_1}\right)^{1/2} \quad (4)$$

The radial equation of motion in the Schwarzschild metric is

$$\frac{1}{2} \left(\frac{dr}{d\tau}\right)^2 + \frac{1}{2} \frac{l^2}{r^2} - GM \left(\frac{1}{r} + \frac{l^2}{r^3}\right) = \frac{1}{2} (e^2 - 1) \quad (5)$$

For radial motion, $l = 0$ so we get

$$\frac{1}{2} \left(\frac{dr}{d\tau}\right)^2 = \frac{1}{2} (e^2 - 1) + \frac{GM}{r} \quad (6)$$

$$= GM \left(\frac{1}{r} - \frac{1}{r_1}\right) \quad (7)$$

$$= GM \frac{r_1 - r}{rr_1} \quad (8)$$

To find the time that elapses on the upward leg of the journey, we must evaluate

$$\Delta\tau = \sqrt{\frac{r_1}{2GM}} \int_{r_0}^{r_1} \sqrt{\frac{r}{r_1-r}} dr \quad (9)$$

This is, as Moore says, a bit of a nasty integral. Using software produces a bit of a jumble, so I resorted to the old-fashioned method of looking the integral up in a table, which produced a somewhat nicer result. We get

$$\Delta\tau = \sqrt{\frac{r_1}{2GM}} \left[-\sqrt{r(r_1-r)} - r_1 \arctan\left(-\sqrt{\frac{r}{r_1-r}}\right) \right]_{r_0}^{r_1} \quad (10)$$

$$= \sqrt{\frac{r_1}{2GM}} \left[-\sqrt{r(r_1-r)} + r_1 \arctan\sqrt{\frac{r}{r_1-r}} \right]_{r_0}^{r_1} \quad (11)$$

At the upper limit, the first term is zero and the second term is

$$r_1 \arctan(\infty) = \frac{\pi}{2} r_1 \quad (12)$$

so the result is

$$\Delta\tau = \sqrt{\frac{r_1}{2GM}} \left[\sqrt{r_0(r_1-r_0)} - r_1 \arctan\sqrt{\frac{r_0}{r_1-r_0}} + \frac{\pi}{2} r_1 \right] \quad (13)$$

Here we're assuming that the arctan lies in the range $[-\frac{\pi}{2}, \frac{\pi}{2}]$. The total time is twice this, so

$$\tau = \sqrt{\frac{2r_1}{GM}} \left[\sqrt{r_0(r_1-r_0)} - r_1 \arctan\sqrt{\frac{r_0}{r_1-r_0}} + \frac{\pi}{2} r_1 \right] \quad (14)$$
