The crude calculation presented earlier gives the energy at infinity of a particle created near the event horizon of a black hole as

$$E_{\infty} = \frac{\hbar}{4GM} \quad (1)$$

In GR units

$$\hbar = 3.5153 \times 10^{-43} \text{ kg m} \quad (2)$$

$$E_{\infty} = \frac{8.788 \times 10^{-44}}{GM} \text{ kg} \quad (3)$$

For a solar mass black hole $GM = 1477 \text{ m}$, so

$$E_{\infty} = 5.95 \times 10^{-47} \text{ kg} \quad (4)$$

In other units, this is (using $1 \text{ eV} = 1.602 \times 10^{-19} \text{ J}$)

$$E_{\infty} = mc^2 \quad (5)$$

$$= 5.355 \times 10^{-30} \text{ J} \quad (6)$$

$$= 3.34 \times 10^{-11} \text{ eV} \quad (7)$$

This is an almost unimaginably small energy. For comparison, the energy of a single photon of visible light (with a wavelength of 500 nm) is around 2.5 eV:

$$E = h\nu = \frac{hc}{\lambda} = 6.626 \times 10^{-34} \times \frac{3 \times 10^8}{5 \times 10^{-7} \times 1.602 \times 10^{-19}} \text{ eV} = 2.48 \text{ eV} \quad (8)$$
